PCD7.L121 -Input / Output „RIO" module with 4 digital inputs 24 VAC/DC and 2 Relays 250 VAC/16 A -Application module for operation mode "Light" and "Blinds"

Description The RIO module was developed as a S-Bus data node for local switching tasks. Via a DDC of the type PCDx / PCS1, inputs can be read and manual/auto function monitored. Two address switches $(\times 1 / \times 10)$ on the front panel allow module addressing and identification. Addresses can be set between 00 and 99 . Up to 100 RIO modules and a maximum of 3 PCD stations can be connected to one bus branch simultaneously. If the bus cycle time is critical, fewer than 30 slaves should be operated in one segment.

without space

Mounting and commissioning to be conform with current regulations:

1. Power-off the installation
2. Place module onto the place of destination
3. Cable with max. single wire $1,5 \mathrm{~mm}^{2}$ insert into
the unit. With consideration of the protection class.
4. Connect the wires into the spring terminals

Connect supply voltage and field bus to the dedicated spring terminals.

## Caution!!

Do not exchange the bus and supply spring
terminals.

## Connectiondiagramm

Operation behaviour "RIO" mode
The device works as an independent input/output module. The input information will be transmit to the master station by the S-Bus protocol. The relay output will switch on/off depending of the master station demands.
Operation behaviour "application" mode
The input information switches the relay outputs direct depending on the choosen application form. On a input information follows a direct relay reaction without delay time. Application forms "light" and "blind" are choosable. At every time the master station is able to have influence into the relay condition.
